AN ENZYME EXHIBITING CELLULASE ACTIVITY

FIELD OF THE INVENTION

- 5 The present invention relates to an enzyme exhibiting cellulase activity, a DNA construct encoding the enzyme, a cellulolytic agent comprising the enzyme and a detergent composition containing the enzyme.

10 BACKGROUND OF THE INVENTION

- Biomass which largely consists of cellulose, hemicellulose and lignin has attracted increasing attention as an important renewable source of energy (including nutritional energy). The amount of carbon fixed by photosynthesis has been estimated to be 100×10^9 tons per year worldwide, and half of that is contained in cellulose. If this material, or at least a significant part of it, could be converted into liquid fuel, gas and feed protein, this would constitute a significant contribution to solving the problem of recycling and conservation of resources. However, it has been found difficult to develop an economically viable process of converting cellulosic material into fermentable sugars.
- 25 The currently most promising of the suggested processes involves the use of enzymes which are able to degrade cellulose. These enzymes which are collectively known as cellulases are produced by a number of microorganisms, including fungi (e.g. Trichoderma reesei, Hemicella insolens, Fusarium oxysporum, etc.) and bacteria (e.g. Clostridium thermocellum, Cellulomonas spp., Thermonospora spp., Bacterioides spp., Microbispora bispora, etc.). The economics of the production of fermentable sugars from biomass by means of such enzymes is not yet competitive with, for instance, the production of glucose from starch by means of α -amylase due to the inefficiency of the cellulase enzymes. The most significant problems connected with the use of cellulases is their low specific activity and the high cost of

their production. Therefore, there is a need to develop cellulases which are more efficient in degrading cellulosic materials into fermentable sugars.

5 Apart from their utility for the degradation of biomass, cellulases have also been suggested for use in detergent compositions for the treatment of cotton-containing fabrics which largely consist of cellulose. It is well known that repeated washing of cotton-containing fabrics generally causes
10 a pronounced, unpleasant harshness in the fabric due to the presence of amorphous regions in the cellulose fibres, which regions form protruding parts on the otherwise smooth fibres. Several methods for overcoming this problem have previously been suggested. For example, US 1.368.599 of Unilever Ltd. teaches
15 the use of cellulases for reducing the harshness of cotton-containing fabrics. Also, US 4.435.307 (of Novo Industri A/S) teaches the use of a cellulytic enzyme derived from Humicola insolens as well as a fraction thereof as a harshness reducing detergent additive. Other uses of cellulases mentioned in the
20 art include soil removal from and colour clarification of fabric (cf. for instance EP 220 016).

Although the use of cellulase enzymes for harshness reduction of cotton-containing fabrics was suggested and demonstrated nearly
25 20 years ago the mechanism of this process has not been elucidated and is still not known in detail. Among other things, this is due to the multiplicity of the enzymes and the enzyme-catalyzed reactions involved. As a matter of fact, cellulases generated in nature e.g. by microbial species are indeed complex
30 mixtures of cellulases. Accordingly, the conversion of naturally occurring materials, like cotton, catalyzed by cellulases is exceedingly difficult to analyze in detail.

Due to these circumstances, the practical exploitation of
35 cellulases for harshness reduction and prevention as well as colour clarification, however desirable, has not become widespread and of great practical utility: it is difficult to

optimise production of multiple enzyme systems and thus to implement industrial cost-effective production of cellulase enzymes, and their actual use has been hampered by difficulties arising from the need to employ rather large quantities of the cellulases to achieve the desired reduction and prevention of the harshness of cotton fabrics: for instance, addition of large quantities of the enzymes to detergent compositions is not compatible with the optimal function of other ingredients in the detergent formulation nor is the addition of very large quantities of enzymes to the detergent composition in the interests of, e.g., consumer safety.

The object of the present invention is therefore to provide cellulase enzymes with a high specific activity.

15

SUMMARY OF THE INVENTION

The present invention relates to an enzyme which exhibits cellulase activity, which enzyme is producible by a strain of Bacillus spp., NCIMB 40250, or by a related Bacillus spp. strain, or a derivative of said cellulase. The strain NCIMB 40250 was deposited on 18 January, 1990, in the National Collection of Industrial and Marine Bacteria, 23 St Machar Drive, Aberdeen, Scotland, UK, in accordance with the provisions of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purpose of Patent Procedure.

In the present context, the expression "enzyme exhibiting cellulase activity" is meant to be understood as an enzyme which is involved in the process of cellulose degradation. There are three different types of cellulases which act synergistically to produce soluble sugars: endoglucanases which show affinity for cellulose and which attack amorphous regions of low crystallinity in the cellulose fibre resulting in the formation of free ends; exoglucanases which initiate degradation from the non-reducing chain ends by removing cellobiose units; and β -glucosidases which hydrolyse cellobiose to glucose.

- The expression "related Bacillus spp. strain" is intended to indicate a strain belonging to the same Bacillus species as the strain NCIMB 40250 or a strain of a closely related species. The species to which the strain NCIMB 40250 belongs has been identified as Bacillus lautus. The scope of the present invention is also intended at least to include cellulase enzymes producible by other Bacillus lautus strains than NCIMB 40250.
- 10 The term "derivative" is intended to indicate a protein which is derived from the native protein by addition of one or more amino acids to either or both the C- and N-terminal end of the the native protein, substitution of one or more amino acids at one or a number of different sites in the native amino acid
- 15 sequence, deletion of one or more amino acids at either or both ends of the native protein or at one or more sites in the amino acid sequence, or insertion of one or more amino acids at one or more sites in the native amino acid sequence.
- 20 Although the enzyme of the invention may be produced by cultivating the Bacillus spp. strain NCIMB 40250 or a related strain and isolating the enzyme from the culture, it will generally be more advantageous to produce the enzyme by recombinant DNA techniques which make it possible to optimize
- 25 the yield of the enzyme produced. Furthermore, cloned genes encoding the enzymes may be modified in order to provide enzymes with improved properties.
- Thus, in another aspect, the present invention relates to a DNA
- 30 construct which comprises a DNA sequence encoding an enzyme exhibiting cellulase activity, which enzyme is derivable from a strain of Bacillus spp., NCIMB 40250, or a related Bacillus spp. strain, or a derivative of said cellulase. The invention further relates to an expression vector which carries an inserted DNA
- 35 construct as indicated above, as well as to a cell transformed with the DNA construct or with the vector.

In a still further aspect, the invention relates to a cellulolytic agent capable of degrading amorphous regions of cellulose fibres, the agent comprising an enzyme exhibiting cellulase activity as defined above.

5

The invention also relates to a detergent composition comprising the cellulolytic agent. The cellulase enzyme of the invention has surprisingly been found to be more stable during washing (for 60 minutes at 40°C) in the presence of conventional
10 detergents than a commercial cellulase preparation (Celluzyme™, a cellulase preparation isolated from Humicola insolens, available from Novo Nordisk, A/S). The cause of the increased stability may reside in the alkalophilic nature of the enzyme (see example 5 below). It is further speculated that it may also
15 be ascribed to stability towards oxidation or towards the proteases commonly included in detergents. If so, the cellulase enzyme of the invention may also show increased storage stability in liquid detergents containing proteases.

20 DETAILED DISCLOSURE OF THE INVENTION

The cellulase enzyme of the present invention is preferably one which exhibits endoglucanase activity (referred to in the following as an endoglucanase), in particular one which exhibits
25 an endoglucanase activity of at least about 10, more preferably at least about 20, most preferably at least about 25, such as about 30, CMC-endoase units per mg of total protein under alkaline conditions. The endoglucanase activity is determined as the viscosity decrease of a solution of carboxymethyl cellulose
30 (CMC) after incubation with the enzyme of the present invention under the following conditions:

A substrate solution is prepared, containing 35 g/l CMC (Hercules 7 LFD) in 0.1 M tris buffer at pH 9.0. The enzyme sample
35 to be analyzed is dissolved in the same buffer.

10 ml substrate solution and 0.5 ml enzyme solution are mixed

and transferred to a viscosimeter (e.g. Haake VT 181, NV sensor, 181 rpm), thermostated at 40°C.

Viscosity readings are taken as soon as possible after mixing
5 and again 30 minutes later. The amount of enzyme that reduces the viscosity by one half under these conditions is defined as 1 CMC-endoase unit.

It should be noted that the endoglucanase of the invention is
10 one which is active (in terms of CMC-endoase activity) under alkaline conditions. More specifically, the endoglucanase is one which has a pH optimum at a pH of about 7.5-10.5. Contrary to several known cellulases which are active at an acid pH and relatively inactive at alkaline pH values, this characteristic
15 makes the endoglucanase of the invention particularly useful for washing purposes, in particular as an ingredient of a detergent composition, as washing of clothes is typically conducted under alkaline conditions due to the alkalinity of most washing detergents. Alkalophilic cellulases are known, e.g. from EP 271
20 004, but they are not indicated to have a high affinity for cellulose, which is the case with the cellulase enzyme of the present invention which also exhibits a higher specific activity.

25 The enzyme of the present invention is preferably one which is active at the temperatures at which clothes are typically washed, which is usually a temperature of up to about 60°C. Thus, the native enzyme isolated from strain NCIMB 40250 is active at temperatures between about 45 and 65°C. This, however,
30 does not preclude the possibility that the enzyme may, under certain conditions, be active at temperatures above 65°C.

One enzyme according to the invention is an endoglucanase with
an apparent molecular weight of 75 kD or a cleavage product
35 thereof exhibiting endoglucanase activity. The term "cleavage product" is intended to indicate a shorter form of the enzyme resulting from, for instance, chemical or enzymatic cleavage

(e.g. by means of a suitable protease) after recovery of the enzyme or from posttranslational processing by the organism producing the enzyme, e.g. N- and/or C-terminal processing, which may give rise to a mature form of the enzyme. A specific
5 example of a cleavage product of the ~75 kD enzyme which is of interest for the present purpose is a product of approximately 58 kD produced on cultivating a host organism transformed with DNA encoding the ~75 kD enzyme. The ~75 kD enzyme (and its ~58
10 kD cleavage product) are referred to in the following examples as Endo1.

The enzyme of the invention may be an endoglucanase encoded by the DNA sequence shown in the appended Sequence Listing ID#1 (showing the sequence of the ~75 kD enzyme), or a modification
15 thereof encoding a derivative of said endoglucanase.

Endoglucanase derivatives may conveniently be provided by suitably modifying the DNA sequence coding for the native endoglucanase. Examples of suitable modifications of the DNA
20 sequence are nucleotide substitutions which do not give rise to another amino acid sequence of the endoglucanase, but which may correspond to the codon usage of the host organism into which the DNA construct is introduced or nucleotide substitutions which do give rise to a different amino acid sequence and
25 therefore, possibly, a different polypeptide structure without, however, impairing the properties of the endoglucanase. Other examples of possible modifications are insertion of one or more nucleotides into the sequence, addition of one or more nucleotides at either end of the sequence and deletion of one or
30 more nucleotides at either end of or within the sequence. Such modifications of DNA coding for native proteins are well known and widely practised in the art.

Another enzyme according to the invention is an endoglucanase
35 with an apparent molecular weight of 56 kD or a cleavage product thereof (as defined above) exhibiting endoglucanase activity. In example 2 below, this enzyme is referred to as Endo2.

The enzyme of the invention may be an endoglucanase encoded by the DNA sequence shown in the appended Sequence Listing ID#3 (showing the sequence of the ~56 kD enzyme), or a modification thereof (as defined above) encoding a derivative (as defined above) of said endoglucanase.

A further enzyme according to the invention is an endoglucanase with an apparent molecular weight of 45 kD or a cleavage product thereof (as defined above) exhibiting endoglucanase activity. A specific example of such a cleavage product is a protein of approximately 30 kD produced on cultivating a host organism transformed with DNA encoding the ~45 kD enzyme. In example 3 below, the ~45 kD enzyme is referred to as Endo3A.

15

The enzyme of the invention may be an endoglucanase encoded by the DNA sequence shown in the appended Sequence Listing ID#5 (showing the DNA sequence encoding the ~45 kD product), or a modification thereof (as defined above) encoding a derivative (as defined above) of said endoglucanase.

Other enzymes exhibiting endoglucanase activity produced from endoglucanase clone 3 (cf. example 3 below) are proteins of approximately 60 and 56 kD, referred to as Endo3B and Endo3C, respectively.

A still further enzyme according to the invention is an endoglucanase with an apparent molecular weight of 92 kD or a cleavage product thereof (as defined above) exhibiting endoglucanase activity. In example 4 below, this enzyme is referred to as Endo4. Other enzymes exhibiting endoglucanase activity produced from endoglucanase clone 4 (cf. example 4 below) are proteins of approximately 74 and 71 kD. Either or both of these may be individual enzymes or cleavage products of the ~92 kD enzyme.

It has been found that enzymes of the invention, e.g. Endo1 and Endo3A, are composed of a core region comprising the catalytically active domain and a region comprising a domain whose function is to mediate binding to cellulosic substrates (i.e. the cellulose-binding domain; this corresponds to a similar domain in an endocellulase from Bacillus subtilis (Nakamura et al., 1987). For example, the full-length ~75 kD form of Endo1 comprises a core region and a C-terminal cellulose-binding domain which, in some cases, may be cleaved off proteolytically leaving a core region of ~58 kD. The presence of the cellulose-binding domain has been found to be important for obtaining a colour clarification effect in prewashed textiles (cf. example 6 below).

Based on this finding, it may be possible to generate novel derivatives of cellulase enzymes which, for instance, combine a core region derived from an endoglucanase of the present invention with a cellulose-binding domain derived from another cellulase enzyme (e.g. one derived from a Cellulomonas fimi cellulase). Alternatively, it may be possible to combine a core region derived from another cellulase enzyme with a cellulose-binding domain derived from an endoglucanase of the present invention. In a particular embodiment, the core region may be derived from a cellulase enzyme which does not, in nature, comprise a cellulose-binding domain, and which is C-terminally extended with a cellulose-binding domain derived from an endoglucanase of the present invention. In this way, it may be possible to construct cellulase enzymes with improved binding properties.

30

The DNA construct of the invention may be one which comprises a DNA sequence encoding any one of the enzymes described above, or derivatives of these enzymes as defined above. The DNA construct may be of genomic or cDNA origin, for instance obtained by preparing a genomic or cDNA library of an appropriate Bacillus spp. strain (e.g. strain NCIMB 40250 or a related strain) and screening for DNA sequences coding for all or part of the

appropriate cellulase by hybridization using synthetic oligonucleotide probes in accordance with standard techniques (cf. Maniatis et al., 1982).

5 The expression vector of the invention carrying the inserted DNA construct encoding the enzyme of the invention may be any vector which is capable of replicating autonomously in a given host organism, typically a plasmid or bacteriophage. In the vector, the DNA sequence encoding the enzyme of the invention should be
10 operably connected to a suitable promoter sequence. The promoter may be any DNA sequence which shows transcriptional activity in the host cell and may be derived from genes encoding proteins either homologous or heterologous to the host organism. The promoter is preferably derived from a gene encoding a protein
15 homologous to the host organism. Examples of suitable promoters are lac of E.coli, dagA of Streptomyces coelicolor and amyl of Bacillus licheniformis.

The expression vector of the invention further comprises a DNA
20 sequence enabling the vector to replicate in the host cell. Examples of such sequences are the origins of replication of plasmids pUC19, pACYC177, pUB110 and pIJ702.

The expression vector may further comprise a DNA sequence coding
25 for a signal peptide in order to provide extracellular expression of the enzyme. The DNA sequence may, for instance, be the signal sequence from the α -amylase gene of B. licheniformis.

The vector may also comprise a selectable marker, e.g. a gene
30 whose product confers antibiotic resistance, such as ampicillin, chloramphenicol or tetracycline resistance, or the dal genes from B.subtilis or B.licheniformis.

The procedures used to ligate the DNA sequences coding for the
35 enzyme of the invention and the promoter, respectively, and to insert them into suitable vectors containing the information necessary for replication in the host cell, are well known to

persons skilled in the art (cf., for instance, Maniatis et al., op.cit.).

5 The host cell of the present invention may be transformed with the DNA construct of the invention encoding the cellulase enzyme described above. In this case, the DNA construct may conveniently be integrated in the host chromosome which may be an advantage as the DNA sequence coding for the cellulase is more likely to be stably maintained in the cell. Integration of
10 the DNA constructs into the host chromosome may be performed according to conventional methods, e.g. by homologous recombination.

15 Alternatively, the host cell may be transformed with an expression vector as described above.

The host cell used in the process of the invention may be any suitable bacterium which, on cultivation, produces large amounts of the enzyme of the invention. Examples of suitable bacteria
20 may be grampositive bacteria such as bacteria belonging to the genus Bacillus, e.g. Bacillus subtilis, Bacillus licheniformis, Bacillus lentus, Bacillus brevis, Bacillus stearothermophilus, Bacillus alkalophilus, Bacillus amyloliquefaciens, Bacillus coagulans, Bacillus circulans or Bacillus lautus, or
25 gramnegative bacteria such as Escherichia coli. The transformation of the bacteria may for instance be effected by protoplast transformation or by using competent cells in a manner known per se.

30 In a yet further aspect, the present invention relates to a method of producing a cellulase enzyme of the invention, which method comprises cultivating a host cell as described above under conditions conducive to the production of the cellulase or derivative thereof and recovering the cellulase or derivative
35 thereof from the cells and/or culture medium.

The medium used to cultivate the cells may be any conventional

medium suitable for growing bacteria. The cellulase may be recovered from the medium by conventional procedures including separating the cells from the medium by centrifugation or filtration, if necessary after disruption of the cells, precipitating the proteinaceous components of the supernatant or filtrate by means of a salt, e.g. ammonium sulphate, followed by purification by a variety of chromatographic procedures, e.g. ion exchange chromatography, affinity chromatography, or the like.

10

In a particular embodiment of the method of the invention, the cellulase is recovered in mature form, either as a result of posttranslational processing of a proenzyme as explained above or as a result of appropriate modifications of the DNA sequence encoding the enzyme in the form of deletions of DNA corresponding to truncations in the N- and/or C-terminal sequences of the enzyme.

There is reason to believe that different cellulases may exert a synergistic effect with respect to the degradation of cellulose. The cellulolytic agent of the invention may therefore advantageously comprise a combination of two or more cellulase enzymes of the invention or a combination of one or more cellulase enzymes of the invention with one or more other enzymes exhibiting cellulase activity. Such cellulases may be endocellulases or exocellulases dependent on the intended use of the cellulolytic agent (e.g. the degree of cellulose degradation aimed at). The other cellulases may be selected from those which may be isolated from species of Humicola such as Humicola insolens (e.g. strain DSM 1800), Fusarium such as Fusarium oxysporum (e.g. strain DSM 2672), Myceliophthora such as Myceliophthora thermophile, Erwinia such as Erwinia chrysanthemum (cf. M.H. Boyer et al., Eur. J. Biochem. 162, 1987, pp. 311-316), Trichoderma such as Trichoderma reesei, Microbispora such as Microbispora bisporea, Neocallimastix such as Neocallimastix frontalis, Piromonas such as Piromonas communis, Robillarda spp., Cellulomonas such as Cellulomonas

fimi, Clostridium such as Clostridium thermocellum, Pseudomonas spp., Thermonospora spp., Bacterioides spp. or Ruminococcus spp.

The cellulolytic agent of the invention may suitably be in the
5 form of a non-dusting granulate, stabilized liquid or protected
enzyme. Non-dusting granulates may be produced e.g. according to
US 4,106,991 and 4,661,452 (both to Novo Industri A/S) and may
optionally be coated by methods known in the art. Liquid enzyme
10 preparations may, for instance, be stabilized by adding a polyol
such as propylene glycol, a sugar or sugar alcohol, lactic acid
or boric acid according to established methods. Other enzyme
stabilizers are well known in the art. Protected enzymes may be
prepared according to the method disclosed in EP 238,216.

15 The cellulolytic agent may suitably exhibit an endoglucanase
activity of 500-10,000 CMC-endoase units (as defined above) per
gram of the agent. The cellulolytic agent is suitably a
detergent additive which may comprise one or more other
enzymes, such as a protease, lipase and/or amylase,
20 conventionally included in detergent additives.

The detergent composition of the invention comprising the
cellulolytic agent described above additionally comprises one or
more surfactants which may be of the anionic, non-ionic,
25 cationic, amphoteric, or zwitterionic type as well as mixtures
of these surfactant classes. Typical examples of anionic
surfactants are linear alkyl benzene sulfonates (LAS), alpha
olefin sulfonates (AOS), alcohol ethoxy sulfates (AES) and
alkali metal salts of natural fatty acids.

30 The detergent composition of the invention may contain other
detergent ingredients known in the art as e.g. builders,
bleaching agents, bleach activators, anti-corrosion agents,
sequestering agents, anti soil-redeposition agents, perfumes,
35 enzyme stabilizers, etc.

The detergent composition of the invention may be formulated in

any convenient form, e.g. as a powder or liquid. The enzyme may, if required, be stabilized in a liquid detergent by inclusion of enzyme stabilizers as indicated above. Usually, the pH of a solution of the detergent composition of the invention will be
5 7-12 and in some instances 7.0-10.5. Other detergent enzymes such as proteases, lipases or amylases may be included in the detergent composition of the invention, either separately or in a combined additive as described above.

10 The softening, soil removal and colour clarification effects obtainable by means of the cellulase enzyme of the invention generally require a concentration of the cellulase in the washing solution corresponding to an endoglucanase activity of
15 5 - 200 CMC-endoase units per liter. The detergent composition of the invention is typically employed in concentrations of 0.5 - 20 g/l in the washing solution. Consequently, the cellulase concentration of the detergent composition of the invention is about 0.3 - 400 CMC-endoase units per gram. In general, it is most convenient to add the detergent additive in amounts of 0.1
20 - 5 % w/w or, preferably, in amounts of 0.2 - 2 % of the detergent composition. For special applications, however, for instance when the detergent composition is to be used for colour clarification or harshness reduction of fabric which has been damaged by repeated washing, it may be convenient to include a
25 much larger amount of the cellulolytic agent, such as about 20% w/w.

In a still further aspect, the present invention relates to a method of reducing the rate at which cellulose-containing
30 fabrics become harsh or of reducing the harshness of cellulose-containing fabrics, the method comprising treating a cellulose-containing fabric with a cellulolytic agent as described above. The method of the invention may be carried out by treating cellulose-containing fabrics during washing. The cellulolytic
35 agent may either be added as such in the amount required to obtain the desired effect, or it may be added as an ingredient of a detergent composition as described above. However, if

desired, treatment of the fabrics may also be carried out during soaking or rinsing or simply by adding the cellulolytic agent to water in which the fabrics are or will be immersed.

- 5 The cellulolytic agent of the invention may also be employed to obtain colour clarification of cellulose-containing fabrics. After repeated washing, such fabrics often develop a grayish appearance. This effect is particularly evident with coloured fabrics, especially dark fabrics, and may probably be ascribed
10 to undyed parts of the cellulose fibres becoming apparent when the cellulose fibres of which the fabric is composed are damaged by mechanical forces. The damaged parts of the fibres are assumed to be more amorphous than intact cellulose fibres and therefore more susceptible to the action of the cellulases of
15 the present invention. The colour clarification effect is more pronounced when the cellulolytic agent contains an endoglucanase which comprises a cellulose-binding domain (cf. example 6 below).
- 20 Accordingly, the present invention further relates to a method of treating a coloured, cellulose-containing fabric in order to provide colour clarification, the method comprising treating the cellulose-containing fabric with a cellulolytic agent according to the invention. The method of the invention may be carried out
25 by treating cellulose-containing fabrics in an aqueous medium during washing. The cellulolytic agent may either be added as such in the amount required to obtain the desired effect, or it may be added as an ingredient of a detergent composition as described above. However, if desired, treatment of the fabrics
30 may also be carried out during soaking or rinsing or simply by adding the cellulolytic agent to water in which the fabrics are or will be immersed. For colour clarification purposes, the aqueous medium may suitably exhibit an endoglucanase activity of more than about 250 CMC-endoase units per liter of the aqueous
35 medium.

It may furthermore be possible to employ a cellulolytic agent

according to the invention to provide a localized variation in the colour of a fabric to impart a "stone-washed" appearance to the fabrics (for the use generally of cellulase enzymes for this purpose, see for instance EP 307 564).

5

The cellulolytic agent of the invention is also contemplated to be useful in the field of paper pulp processing, e.g. pulp drainage (for the use generally of cellulase enzymes for this purpose, see for instance EP 262 040), as well as for deinking
10 of paper intended for recycling (for the use generally of cellulase enzymes for this purpose, see for instance JP 59-9299 or JP 63-59494).

The invention is further illustrated by the following examples
15 which are not in any way intended to limit the scope of the invention, with reference to the appended drawings, wherein

35

EXAMPLESMATERIALS AND METHODS5 a) Bacterial strains and plasmids

The donor strain, Bacillus spp., strain PL236, was isolated from a compost sample from Lyngby, Denmark, on the basis of its high cellulolytic activity. A sample of this strain was deposited on 18th January, 1990 in the National Collection of Industrial and
10 Marine Bacteria, 23 St. Machar Drive, Aberdeen, Scotland, with the accession No. NCIMB 40250.

The following E. coli strains and plasmid were used: MC 1000 (araD139), (ara, leu)7697, lacX74, galU, galK, rpsL) (Casaba-
15 dan et al., 1980); CSR603 (F-, thr-1, leuB6, proA2, prh-1, RecA1, argE3, thi-1, uvrA6, ara-14, lacY1, galK2, xyl-5, mtl-1, rpsL31, tsx-33, -, supE44) (Sancar et al., 1979); PL248 is MC1000 containing the plasmid pNF2690 which contains the replication origin and the kanamycin resistance gene from
20 pACYC177 (Chang and Cohen, 1978) and the cI857 repressor gene from the coliphage lambda; pBR322 (Bolivar, 1977); pUN121 (Nilsson et al., 1983) pUC18 (Yanisch-Perron et al., 1985); pPLc28 (Remaut et al., 1981); pPL170 (Jørgensen, P.L., 1983);

25 For the experiments with B. subtilis, the following B. subtilis strains and plasmids were used: DN1885 (amyE, amyR, spo⁺, pro⁺) (Diderichsen, Novo Industri A/S) is a derivative of B. subtilis 168; PL1801 is a derivative of DN1885 lacking the two main exoproteases (apr⁻, npr⁻); pDN2801 has the origin of replication
30 from pUB110 (Keggins et al., 1987), the Cat gene of pC194 (Horinouchi and Weisblum, 1982) and the maltogenic alpha-amylase promotor (Pm) from B. stearothermophilus (Diderichsen and Christiansen, 1988) followed by a polylinker; The B. subtilis/E.coli shuttle vector pJKK3-1 is described by Kreft et al.
35 (1983); pPL1759 has the origin and kanamycin resistance gene of

pUB110 and the promotor, ribosome binding site and signal sequence from the alpha-amylase gene from B.licheniformis (Stephens et al., 1984).

5 b) Media

Phosphoric acid swollen cellulose (ASC) was prepared from chromatography cellulose (MN 300, Machery, Nagel) as described by Walseth (1952) with the exception that the cellulose powder
10 was suspended in acetone before treatment with phosphoric acid. The medium for detection of cellulase activity was prepared as standard m)-medium (Maniatis et al., 1982) containing 0.2% ASC or microcrystalline cellulose (Avicel, Merck).

15 Bacillus spp., B.subtilis and E.coli cells were grown in NY medium (von Meyenburg et al., 1982), LB medium (Maniatis et al., 1982), or BPX medium (100 g/l potato starch, 50 g/l barley flour, 0.1 g/l BAN 5000 SKB, 10 g/l sodium caseinate, 20 g/l soybean meal; 9 g/l Na₂ HPO₄, 12H₂O, 0.1 g/l Pluronic).

20

The media were solidified by the addition of agar (20 g/l).

Tetracycline (20µg/ml), or kanamycin (10 µg/ml) were added as required.

25

c) Isolation of DNA

To isolate the chromosomal DNA from Bacillus spp. PL236, cells from 250 ml overnight culture were resuspended in 10 ml (50 mM Tris-HCl, pH 8.0, 100 mM EDTA), and incubated with 25 mg
30 lysozyme for 20 min. at 37°C. To the mixture was added 2 ml of 10% (w/v) SDS, mixed and put on ice for 10 min. To the solution was then added 15 ml of phenol saturated with TE-buffer (10 mM Tris-HCl, pH 8.0, 1 mM EDTA), heated to 65°C, mixed gently and cooled on ice. After centrifugation for 30 min. at 40000 g the
35 aqueous phase was ether extracted, ethanol precipitated and the

pellet was resuspended in TE-buffer. The DNA was further purified by banding in a CsCl density gradient (Maniatis et al., 1982).

- 5 E.coli plasmid DNA was prepared by the SDS lysis method (Maniatis et al., 1982); minipreparations of plasmid DNA for restriction enzyme analysis and transformations were prepared according to Holmes and Quigley (1981). B.subtilis plasmid DNA was prepared by the alkaline lysis method. (Maniatis et al.,
10 1982).

d) Cloning of chromosomal DNA from Bacillus spp. PL236 into E. coli

- Restriction enzymes and T4 DNA ligase were obtained from New
15 England Biolabs and used as described by the manufacturers. After digestion with PstI, EcoRI or HindIII restriction enzyme the DNA was heated to 65°C for 10 min. and ethanol precipitated. 10 µ of linearized pBR322, pJKK3-1 or pUN121 and 20 g of fragmented B. spp. chromosomal DNA were ligated with 5 units of
20 DNA ligase in a final volume of 100 µl (16 h, 15°C). The ligated DNA was used to transform competent E.coli MC1000 to tetracycline resistance essentially as described by Mandel and Higa (1970). (pBR322: 20 µg/ml, pUN121: 7 µg/ml and pJKK3-1: 10 µg/ml).

25

e) Detection of cellulase-positive E.coli clones

- The detection of cellulase activity on plates was performed using a modification of the technique of Teather and Wood (1982). E.coli clones were grown overnight on solid NY medium at
30 37°C. Cells were lysed by overlaying the colonies by topagar containing phosphate buffer (100 mM, pH 7.0), agar (0.7%) CMC (0.2%), SDS (0.25 mg/ml), and chloramphenicol (200 µ/ml) and subsequent incubation overnight at 37°C. Plates were then flooded with an aqueous solution of Congo red (1 mg/ml) for 15
35 min. and subsequently washed with 1 M NaCl. Cellulase-positive

colonies were surrounded by a yellow halo on a red background.

f) Maxicells

Plasmid-encoded proteins were analysed using the maxicell method of Sancar et al. (1979) with the following modification. After
5 UV irradiation, the surviving cells were killed by incubating the cells with D-cycloserine (150 µg/ml) for 48 h at 37°C.

g) Gel electrophoresis

(³⁵S)-L-methionine labelled maxicell proteins and other proteins
10 were analysed by electrophoresis on 15% (0.075 per cent bisacrylamide) SDS-polyacrylamide gels (Laemmli, 1970). Proteins were visualized either by staining with Coomassie Blue G 250 or by autoradiography.

15 Analysis of DNA was done by electrophoresis on agarose gels with the buffer described by Loening (1967).

h) Detection of cellulase activity in polyacrylamide gels

Detection of cellulase activity in protein bands separated by
20 SDS-polyacrylamide gel electrophoresis was done by a modified zymogram technique described by Beguin (1983). Protein preparations were electrophoresed on a SDS-polyacrylamide gel as described above and the gel was washed 3 times 30 min. in phosphate buffer (100 mM, pH 7.0) layered on to a thin (0.8 mm)
25 agarose gel (agarose, (1.8 per cent), CMC, (0.2 per cent), phosphate buffer, (100 mM, pH 7.0)), and incubated for 4 h at 42°C. Cellulase activity was visualized by staining the agarose gel for 30 min. in an aqueous solution of Congo red (1 mg/ml) followed by washing the gel in 1 M NaCl.

30

i) Colorimetric cellulase assay

Cellulase activity in cell extracts was analysed by measuring the increase in reducing groups released by the hydrolysis of CMC (Miller, 1959). An appropriate amount of enzyme was in-
35 cubated with 1.5 ml of 1 per cent CMC in phosphate buffer (100

mM, pH 7.0). After 30 min. of incubation at 55°C, 1.5 ml of dinitrosalicyclic acid reagent was added and the samples were boiled for 5 min. The absorbance was read at 550 nm against blanks containing equivalent amounts of extract from the E.coli recipient strain. One unit of cellulase released 1 nM of glucose equivalents per second by reference to a standard curve.

j) DNA-Sequencing

Single end labelled DNA fragments were isolated and sequenced by the chemical modification method (Maxam and Gilbert, 1980). The cleavage products were separated on 8% or 20% polyacryl-amide gels and thereafter autoradiographed at -70°C using intensifying screens.

The dideoxyribonucleotide method of Sanger et al., (1977) was used for the sequencing of Endo3A using derivatives of pUC18 (Yanisch-Perron, 1985).

k) Southern-analysis

Chromosomal DNA from Bacillus spp. (PL236) was digested with restriction enzymes as required and fractionated on 1% (w/v) agarose gels. DNA was then blotted onto nitrocellulose filters. ³²P-labelled DNA probes (recombinant plasmids) were prepared by nick translation (Rigby et al., 1977) using ³²P- α -CTP (Amersham) and hybridization was carried out as described by Southern (1975). Autoradiography was performed at -70°C using intensifying screens.

l) Transformation of competent B. subtilis cells

A modified version of Dubnau and Davidoff-Adelson's (1971) procedure for preparing competent cells of B. subtilis is used. 10 ml of LB-medium is inoculated with the strain in the morning. 7 hours later sequential dilutions in KM-1-medium are made and incubated overnight at 37°C. The following morning, the second-most diluted and growing culture is diluted ten times in KM-2-

medium. The cells are harvested after 45-60 minutes of incubation by centrifuging for 3 minutes at 7K. They are resuspended in 1/10 volume of the supernatant and 1/50 volume of 86% glycerol is added. 0.1 ml amounts are frozen on liquid nitrogen and stored at -80°C.

In order to transform these competent cells, the method of Ehrlich (1986) is used, with some modifications. BTF is prepared and preheated to 42°C. 0.01 ml of DNA is placed in a reaction vessel, and the competent cells are thawed at 42°C. BTF is added to the cells at a ratio of 1:1, and 0.1 ml of the mixture is added to the DNA. The cells and DNA incubate with shaking for 20 minutes at 37°C. A further 30 minutes of gene expression with 0.1 ml of NY-medium is needed, if kanamycin resistance is desired. The cells are finally spread on relevant plates. Recipes for stock-solutions are as follows:

Stock solutions for making *B.subtilis* competent cells

20

Salt mix: 10 mM CaCl_2 , 1mM FeCl_3 and 1mM MnCl_2 .

10 X MM: 20 g $(\text{NH}_4)_2\text{SO}_4$, 60 g KH_2PO_4 , 140 g $\text{K}_2\text{HPO}_4 \cdot 3\text{H}_2\text{O}$ in 1L.

25

KM-stock: 100 ml 10 X MM, 10 ml 10% Na-citrate, 2 ml 1M MgSO_4 in 1L.

30

KM1-stock: 960 ml KM-stock, 20 ml 20% glucose, 1 ml 20% casamino acids, 20 ml 5% yeast extract, 30 l 1mM MnCl_2 in 1L.

35

KM2-stock: 960 ml KM-stock, 20 ml 20% glucose, 1 ml 20% casamino acids, 20 ml 5% yeast extract, 1 ml salt mix, 1 ml

25

0.5 M CaCl_2 , and 0.8 ml 1M MgCl_2 in 1L.

BCG:

5

100 ml 10 x MM, 10 ml Na-citrate, 2 ml 1M MgSO_4 , 1 ml saltmix, 20 ml 20% glucose in 1L.

BTF:

10

800 ml BCG, 100 ml 10mM EGTA, 100 mM MgCl_2 in 1L.

(Prepared fresh before use).

ISOLATION AND CHARACTERIZATION OF CELLULOLYTIC STRAINS

15 In order to clone genes coding for cellulose-degrading enzymes the following screening programme was set up to find suitable cellulolytic donor strains. Various compost samples were used as source of cellulolytic microorganisms.

20 Serial dilutions of compost samples were plated out on ASC agar medium and cellulolytic activity was detected through the formation of clearing zones around the colonies. Several cellulolytic bacteria were isolated. One of the most active of these isolates which was identified as Bacillus spp. PL236 (NCIMB 40250) was selected as the donor strain for the cloning
25 experiments.

The strain rapidly degraded both acid swollen cellulose and microcrystalline cellulose (Avicel, Merck) on agar medium. At the optimum temperature of growth (42°C) the clearing zones
30 appeared in 2-3 days.

Adding small amounts of Bacillus spp. PL236 culture to suspensions of microcrystalline cellulose makes the cellulose crystals lump together tightly and sediment.

35

This suggests that either the Bacillus spp. PL236 cells or the extracellular cellulase enzymes have a strong affinity for the cellulose substrate and tightly bind the cellulose crystals together.

5

SCREENING ASSAY FOR RECOMBINANT CLONES

The first attempts to clone cellulases from Bacillus spp. PL236 were directed towards the endocellulases genes from Bacillus spp. PL236. To facilitate the screening on plates of endocellulase positive clones, an assay using the dye Congo red (Teather and Wood, 1982) was adapted to E.coli.

In order to detect cellulase activity trapped inside the recombinant E.coli cells the cells were lysed by adding SDS to the top agar. This modification of the top agar had no measurable effect on the CMC-degrading enzymes of Bacillus spp. PL236, when the modified assay was used on this organism.

20 MOLECULAR CLONING OF ENDOCELLULASES

Several endocellulase genes were cloned from the cellulolytic Bacillus spp. strain (PL236). An endocellulase 1 clone (PL517) was made by ligating PstI partially digested PL236 chromosomal DNA with PstI cleaved pBR322 and subsequently transforming competent E.coli cells.

An endocellulase 2 clone (pPL382) was made by ligating HindIII partially digested PL236 chromosomal DNA with HindIII cleaved pJJK3-1 (an E.coli/B.subtilis shuttle-vector) and subsequently transforming competent E.coli cells.

An endocellulase 3 clone (pPL591) was made by ligating EcoRI partially digested PL236 DNA with EcoRI cleaved pUN121 and subsequently transforming competent E.coli cells.

An endocellulase 4 clone (pPL592) was made by ligating HindIII partially digested PL236 DNA with HindIII cleaved pUN121 and subsequently transforming competent E.coli cells.

5

Transformants derived from the use of both the pBR322 and the pUN121 plasmid vector were screened by their tetracycline resistance (pBR322: 20 g/ml, pUN121: 7 µg/ml and pJKK3-1: 10 µg/ml).

10

The transformants were replicated to another set of plates and overlaid by the modified CMC top agar. The plates were incubated overnight and stained with Congo red as described above.

15 Under the reisolation procedure it was observed that it was possible to detect positive clones without adding the cell lysing agent SDS to the topagar, although the diameter of the halo was considerably smaller.

20 EXPRESSION AND CHARACTERIZATION OF THE CLONED CELLULASES

Plasmids from the cellulase-positive transformants were isolated and analyzed with restriction enzymes. Restriction enzyme maps of representative plasmids from all four cloning experiments are
25 shown in Fig. 1.

To determine the molecular weight of the cloned endoglucanases a zymogram technique (Beguin, 1983) was used. Total protein preparations from representative endoglucanase clones were
30 separated on a SDS-polyacrylamide gel. The proteins in the gel were then renatured by washing out the SDS and replicated onto an agarose gel containing CMC. Renatured proteins diffuse to this activity gel and proteins representing endoglucanase activity hydrolyse the CMC in the gel. The endoglucanase bands
35 were then visualised by staining the activity gel with Congo red

as described above.

As appears from Fig. 1, the restriction maps of the cloned DNA (as well as the molecular weight of the endoglucanases encoded by the cloned DNA) are different in the four different clones. This indicates that these four clones represent at least four different endocellulase genes from Bacillus spp. (PL236).

The detailed analysis of the different endocellulases represented by these four clones is described in the following.

Example 1

Endocellulase 1 (Endol)

Physical mapping of endocellulase gene 1

In the cloning experiment described above several cellulase-positive E.coli clones were obtained, which contained different fragments of PstI partially cleaved Bacillus spp. PL236 DNA. Fig. 2 shows the restriction maps of some of these clones. The plasmids invariably contained two PstI fragments (1000 and 1350 bp.) indicating that both were necessary for synthesis of a polypeptide with cellulase activity: Nucleotide sequencing has later shown that the 500 bp. PstI fragment present on pPL217 and pPL517 (Fig. 2) contains the C-terminal part of the complete cellulase gene (data are presented in the following). The structure of this part of the B.spp. chromosome was confirmed by Southern analysis (data are presented in the following).

Activity measurements

Extracts from the E.coli clones containing pPL212, pPL216, pPL517 and pBR322 were prepared from overnight cultures grown in NY medium supplemented with tetracycline. Cells were concentrated 10-fold in 100 mM phosphate buffer, pH 7.0. DNase was added and the cells were ruptured by passing them twice

through a French Press (12000 lb/in). The extracts were centrifuged for 60 min. at 40000 X g and the supernatants were assayed for cellulase activity. The cell-free extract of *E.coli* MC1000(pPL212), *E.coli* MC1000(pPL517) and *E.coli* MC1000(pPL216) contained 8 units, 7.2 units and 0.2 units respectively of cellulase/ml of original culture volume. (Fig. 2). 1/7 of the total cellulase activity in these cultures was found in the supernatant. The *E.coli* MC1000(pBR322) clone showed no cellulase activity.

10

The high level of cellulase activity in extracts of strains carrying the plasmids pPL212 and pPL517 is most likely due to an increased transcription of the cellulase gene originating from the β -lactamase promoter on pBR322. It was concluded that the cellulase is expressed in the direction shown in Fig. 2.

15

Measurements of the viscosity of a CMC solution and of the release of reducing sugars indicated that the cloned cellulase is an endo-(1,4)- β -glucanase.

20

Maxicell and zymogram analysis

The molecular weight of the endoglucanase protein was analysed by the maxicell technique. The plasmids pPL212, pPL216 and pBR322 were transformed into the maxicell strain CSR603 (Sancar et al., 1979) to analyse for plasmid-encoded proteins. The plasmid pPL212 gave rise to three polypeptides of 75000 D, 65000 D and 58000 D in addition to the proteins encoded by pBR322. Apart from the pBR322 proteins, no proteins encoded by the plasmid pPL216 could be detected, due to the low expression of the cellulase gene. The three polypeptides from pPL212 were tested for cellulase activity using a gel replica technique, (Beguin, 1983).

A comparison of the cellulase activity bands and the bands on

35

the autoradiogram from the polyacrylamide gel showed that the 75000 D and at least one of the 58000 and 65000 D protein bands had cellulase activity. It was also found the supernatant of the Bacillus spp. PL236 culture contained at least three different proteins with cellulase activity. One of these proteins comigrated with the 58000 D protein synthesized in the maxicell. Cell extracts from E.coli MC1000 (pPL212) only revealed one active band comigrating with the 58000 protein from the maxicell E.coli CSR603 (pPL212). As mentioned previously, the following sequence data showed that the plasmids pPL212 and pPL216 did not contain the entire Endo1 endoglucanase gene. The 75000 D active protein seen in the maxicell E.coli CSR603 (pPL212) is thus a fusion protein, where 105 C-terminal amino acids are encoded by pBR322 sequences (Fig. 2). This fusion protein is apparently posttranslationally processed, ending up with the 58000 D mature endoglucanase. Cell extracts from E.coli MC1000 (pPL217) and E.coli MC1000 (pPL517), which contain the complete endoglucanase gene, also gave activity bands of M_r approx 58000 D and 75000 D. The 75000 D active protein from the plasmids pPL217 and pPL517, thus represents the "genuine" initial translation product from the Endo1 glucanase gene, which apparently is processed more slowly than the fusion protein from pPL212. However, both the 75000 D fusion protein synthesized from pPL212 and the "genuine" 75000 D protein synthesized from pPL517 and pPL217 are processed down to a 58000 D protein with high cellulase activity.

From the sequence data it can also be predicted that the endoglucanase expressed from pPL216 is synthesized a fusion protein, where the 26 C-terminal amino acids are encoded by pBR322 sequences (Fig. 2). This protein was not detected by the maxicell technique and zymograms using extract from PL216 only revealed one active band of 58000 D, which most likely represents the processed protein. The processing in E.coli of the two fusion proteins from pPL212 and pPL216, which represent two different lengths of the C-terminal "tail" thus results, in both

case, in an active protein of approx. 58000 D. This indicates that the endocellulase is processed from the C-terminal, because N-terminal processing would result in two proteins with a difference in M_r of approx. 9000 D, which would easily have been
5 detected on the zymograms.

It is therefore most likely that endoglucanase 1 (Endo1) is synthesized as a proenzyme which at least in E.coli (and possibly also in B.spp.) is modified by stepwise removal of
10 approx. 150 C-terminal amino acid residues and approx. 30 N-terminal amino acid residues, corresponding to the removal of the signal peptide. The endoglucanase seems to be modified correctly as indicated by the fact that the final processing product, the 58000 D activity band present in E.coli MC1000
15 (pPL212) extract, apparently comigrate with one of the endoglucanases present in the supernatant of cultures of Bacillus spp. PL236.

Temperature optimum and stability

20 The cellulase activity of the extracts was measured at different temperatures and the highest activity of Endo1 produced in E.coli was found at 60°C (Fig. 3). The heat stability of the endoglucanase was tested by incubating the extracts at 50°C,
25 55°C and 60°C for varying periods and the residual activity was measured as outlined in Materials and Methods. Although the highest activity was observed at 60°C with a fixed incubation time of 30 min., the enzyme is inactivated at this temperature with a $t_{1/2}$ of 1.2 h. At 50°C and 55°C no inactivation was observed
30 after 5 h of incubation.

DNA-sequence

The nucleotide sequence of the endocellulase gene 1 (Endo1) was
35 deduced from the plasmid pPL517 which contains approx. 2850 bp

of Bacillus spp. PL236 DNA.

The sequence was determined by the chemical modification method (Maxam and Gilbert, 1980) using the partial restriction map and
5 the sequencing strategy outlined in Fig. 4.

The complete nucleotide sequence is shown in Sequence listing ID#1. A computer analysis of this sequence revealed only one open reading frame long enough to encode the approx. 75000 D
10 protein detected by the maxicell and zymogram analysis of extracts from the cellulase-positive E.coli MC1000(pPL517). This sequence which begins at nucleotide 677 and ends at nucleotide 2776, encodes an enzyme of 700 amino acids. The M_r calculated from the DNA sequence was 77006 D.

15 Within the open reading frame there were three potential initiation codons (ATG at positions 677, 737 and 749), but only the ATG codon at position 677 was preceeded by a ribosome binding site (AAGGAGG) (McLaughlin et al., 1981). It was therefore
20 concluded that the ATG codon at position 677 was the correct initiation codon.

The initiation codon is followed by an amino acid sequence which resembles signal sequences found in gram-positive organisms.
25 Such sequences consist of a relatively short hydrophilic region at the N-terminal followed by a longer sequence of hydrophobic residues.

By using the signal sequence cleavage model proposed by Heijne
30 (1983) the cleavage site can be predicted to be between the two first alanine residues in the sequence Asn-Ala-Ala-Ala. The signal sequence is thus 31 amino acids long.

The upstream and downstream regions contained no significant
35 homology to the consensus sequence of the sigma 43 promoter of

B. subtilis and no terminator-like sequences.

Southern analysis

5 The Bacillus spp. (PL236) chromosomal DNA was digested with HindIII, PstI, EcoRI and XhoI and plasmids pPL212 and pPL509 were used as probes for the hybridization. Plasmid pPL212 contains two PstI fragments (1350 bp. and 1000 bp.) and plasmid pPL509 contains only the 500 bp. PstI fragment of the entire
10 EndoI gene, represented by the plasmid pPL517, which contains three PstI fragments (1350 bp., 1000 bp. and 500 bp.) of Bacillus spp. PL236 DNA. The pPL212 probe recognized the expected two PstI fragments (1350 bp., 1000 bp.) and the pPL509 the 500 bp. PstI fragment in the Bacillus spp. PL236 PstI
15 digest. Both the pPL212 and the pPL509 probe also recognized the same overlapping EcoRI fragment and the same overlapping HindIII fragment in Bacillus spp. PL236, EcoRI and HindIII digest. These results indicate that the Bacillus spp. PL236 DNA insert in pPL517 was cloned in a non-deleted form and that the three PstI
20 fragments in pPL517 are continuous on the Bacillus spp. PL236 chromosome.

Expression of the EndoI gene in B.subtilis

25 For the cloning experiments in B.subtilis, pPL517 was used as the donor of the EndoI gene and pDN2801, carrying a strong Bacillus promoter P_m, was used as the Bacillus vector (Fig. 5).

The EndoI gene-containing EagI fragment was ligated to EagI
30 cleaved pDN2801 and by subsequent transformation to competent B.subtilis cells (DN1885), strain CH7 was obtained. To test whether the processed C-terminal part was necessary for the expression of the EndoI gene in B.subtilis cells, a construction was made where the EndoI gene was fused to vector sequences in the internal BglII site. This fusion replaces the coding
35

region for the C-terminal 94 amino acids with 55 "random" amino acids encoded by vector sequences.

5 Similar constructions made in E.coli vectors, though fused to different vector sequences, resulted in an active periplasmic endoglucanase in E.coli, which was processed in the "correct" manner. Part of the Endo1 gene contained in the BglII fragment from pPL517 was ligated with BamHI cleaved pDN2801 and subsequent transformation to competent B. subtilis cells (DN1885) 10 resulted in strain CH14.

Transformants were in both cases screened for their chloramphenicol resistance, and the desired plasmid constructions in the strains CH7 and CH14 by restriction analysis of their plasmids. 15 The two versions of the Endo1 gene on the plasmids pCH7 and pCH14 are thus transcribed from the same promoter P_m . A restriction map of the plasmids is shown in Fig. 6.

The B.subtilis DN1885 used for these experiments produces an 20 endoglucanase of its own, which of course gave some background activity. The Endo1 gene product was exported to the culture medium from the recombinant strain CH7, and the activity measured in the culture supernatant was approximately 20 times higher than the background activity (Fig. 6). No extracellular 25 activity above the background level was detected from the recombinant strain CH14 which contains the Endo1 gene with the substituted C-terminal.

The culture supernatants from the strains CH7 and CH14 and cell 30 extract from CH7 cells were analysed by the zymogram technique. The zymogram revealed active protein bands of approx. 75000 D and 58000 D from the CH7 cell extract and only one active protein band of approx. 58000 D from the CH7 culture supernatant. These bands correspond to those observed in E.coli and the 35 processing of approx. 90 amino acids from the C-terminal appears

to take place in B.subtilis too.

The plasmid pCH7 was transformed to PL1801, which is a derivative of DN1885 lacking the two main exoproteases (apr⁻, npr⁻), resulting in the strain CH14. The Endo1 cellulase as produced from CH14 was processed "normally" indicating that the two main exoproteases from B.subtilis are not responsible for the C-terminal processing of the Endo1 cellulase.

A very weak active band of approx. 58000 D was detected from the CH14 culture supernatant, indicating that the manipulated gene is expressed and processed in at least almost the same way as the native gene product. Among other things, the very low expression from pCH14 and the fact that the two genes are expressed from the same expression signals may indicate that the approx. 90 C-terminal amino acids are necessary for the export of the Endo1 gene product from B.subtilis.

Optimization of expression of the Endo1 gene in E. coli

In order to optimize the expression of Endo1, the Endo1 gene was combined with the strong E.coli promoters P_R and P_L originating from phage lambda (Remaut et al., 1981). Both promoters are repressible by the lambda cI857 repressor, which is heat labile, thus rendering the P_R and P_L promoters heat inducible, in cells producing the lambda cI857 gene product. (Ptashne et al., 1982).

The P_R promoter is contained on the expression plasmid pPL170 together with the lambda cI857 gene. (Fig. 7; Jørgensen, 1983).

The P_R promoter was placed upstream of the Endo1 gene by ligating the P_R containing PvuI - SalI fragment from pPL170, to the Endo1 gene containing PvuI - SalI fragment. Transformation to competent MC1000 cells resulted in the strain TL05 containing the plasmid pTL05. In the plasmid pTL05 the β -lactamase promoter

is deleted, thus bringing the Endo1 gene under transcriptional control of the P_R promoter. At this point, the Endo1 gene was believed to be contained within the BglIII fragment from pPL2129. The Endo1 gene fusion to vector sequences on pPL212 was therefore transferred to pTL05, resulting in a fusion protein where 105 C-terminal amino acids are encoded by vector sequences. This fusion protein is however processed correctly as shown earlier with the strain PL212. The cellulase production from TL05 is completely repressed at 28°C and induced at 42°C.

The P_i promoter provided on the plasmid pPLc28 (Remaut et al., 1981) was combined with the Endo1 gene by ligating the BglIII fragment from pPL212 to BamHI cleaved pPLc28. Transforming to competent PL248 cells, which are harbouring the lambda cI857 gene on a compatible pACYC177 based plasmid (pNF2690), resulted in the strain LA03, containing the plasmid pLA03 (Fig. 7). The Endo1 gene is thus fused to vector sequences, but due to unspecified DNA sequences in pPLc28 the length and nature of the resulting fusion protein is unknown. The cellulase production from LA03 was completely repressed at 28°C and induced at 40.5°C.

The cellulase production from LA03 and TL05 was evaluated at different temperatures.

LA03, TL05 and PL212 were grown overnight at 28°C in NY medium supplemented with the appropriate antibiotics (AMP + KAN, KAN and TET, respectively). For each strain the overnight cultures were diluted 100 fold in NY medium (AMP + KAN, KAN and TET, respectively), and the diluted cultures were grown at different temperatures between 28°C and 42°C. Cells from each culture were harvested at $OD_{450} = 1$ and lysed on a French Press, and the activity in the extracts was determined as described earlier.

LA03 which exhibited the highest cellulase production was unable

to grow at temperatures above 40.5°C. The experiment was repeated without antibiotic selection pressure in the diluted cultures. Similar results were obtained, but LA03 grew very slowly at temperatures above 40.5°C. However, this growth was
5 followed by a significant loss of the plasmid pLA03. No significant loss of pLA03 at temperatures up to 40.5°C or pPL212 and pTL05 at any temperature, was observed.

Optimization of expression of the Endo1 gene in B.subtilis

10

In order to optimize the expression of the Endo1 gene in B.subtilis, the Endo1 gene was fused to the expression-signals (promoter, ribosome binding site and signal sequence) from the alpha-amylase gene from B.licheniformis, which is expressed in
15 high amounts in B.subtilis.

pPL1759 contains the promoter, ribosome binding site and most of the signal peptide of the B.licheniformis alpha-amylase (Stephens et al., 1984). The downstream side of this region ends
20 with a PstI site, which again is followed by a polylinker (Fig. 8). Between the PstI and the SalI site in the polylinker of pPL1759, a synthetic DNA fragment consisting of two complementing oligonucleotides creating PstI and SalI "sticky" ends was inserted. In the resulting plasmid pCH52 the synthetic
25 linker reconstitutes the missing part of the signal peptide of the alpha-amylase and further encodes the first 14 N-terminal amino acids of the mature Endo1 cellulase (Fig. 8). The linker thus creates a hybrid signal peptide cleavage site between the alpha-amylase and the cellulase. The expected cleavage site is
30 shown in Fig. 8. From pPL517 the Endo1 gene was excised without promoter on an EagI fragment and inserted into the unique EagI site in pCH52. The plasmid in which the Endo1 gene was inserted in the correct orientation was named pCH54.

35 pCH54 contains two direct repeated sequences of 45 bp (e.g. the

45 N-terminal base pairs of the mature Endo1 gene) which may recombine, deleting the region between them (Ehrlich et al., 1986). This recombination event, however, occurs with a very low frequency when the repeat is as small as 45 bp. In order to
5 enrich the amount of plasmid that has recombined, a plasmid preparation of pCH54 was cut with the enrichment restriction enzyme KpnI. pCH54 contains a unique KpnI site between the two direct repeats and only non-recombinant plasmids are cut with KpnI, while recombinant plasmids stay circular. When B.subtilis
10 (DN 1885) was retransformed with this mixture, transformants were mostly (90%) containing recombinant plasmids, since B.subtilis competent cells are not transformed with linerized plasmid DNA. The recombinant plasmid was called pCH57 and is contained in the strain CH57. The structure was confirmed by
15 restriction analysis, but the gene fusion was not confirmed by DNA sequencing. In this construction pCH57 the Endo1 gene is thus perfectly fused to the alpha-amylase expression signals.

The endoglucanase is produced extracellularly from the B.
20 subtilis strain CH57, indicating that the hybrid signal cleavage site is functioning. The secreted Endo1 endoglucanase is processed to the expected M_r , namely 58000 D.

The production of the Endo1 cellulase from CH57 was evaluated in
25 two different media, NY (overnight at 37°C) and BPX (7 days at 37°C). The BPX medium is a very rich medium in which the nutrients are slowly released, thus keeping the cells in an early stationary fase for several days during fermentation. The alpha-amylase expression signals function particularly well in
30 this medium. The results appear from Table 1 below.

Table 1

| 5 | STRAIN | PLASMID | U/ml | U/ml |
|----|--------|---------|------|-------|
| | | | NY | BPX |
| 10 | CH7 | pCH7 | 6.5 | 55.0 |
| | CH57 | pCH57 | 13.0 | 325.0 |
| | DN1885 | --- | 0.3 | 40.0 |

15 Analysis of the culture supernatant (BPX-medium) on PAGE revealed a dominant (90%) endoglucanase band corresponding to a concentration of endoglucanase in the supernatant of approx. 0.5 g/L.

20 Example 2

Endocellulase 2 (Endo 2)

DNA-sequence

25

The nucleotide sequence of endocellulase 2 (Endo2) was deduced from the plasmid pPL382 which is described above. The plasmid contains approx. 2500 bp. of Bacillus spp. PL236 DNA. The sequence was determined by the chemical modification method (Maxam and Gilbert, 1980) using the partial restriction map and the sequencing strategy outlined in Fig. 9.

30

The complete nucleotide sequence is shown in Sequence Listing ID#3. A computer analysis of this sequence revealed only one open reading frame long enough to encode for the approx. 56000 D protein detected in the zymogram analysis of the extract from

35

the cellulase positive clone E.coli MC1000(pPL382). This sequence begins at position 172 and ends at 1869 and encodes an enzyme consisting of 566 amino acids. The calculated M_r is 62551 D which is slightly higher than the M_r of 56000 D determined by
5 zymogram analysis. This difference could be due to inaccuracy in the zymogram analysis or to post-translational processing beyond the expected processing of the signal peptide. The ATG initiation codon in position 172 was selected because it was the only initiation codon within the open reading frame, which was
10 proceeded by a ribosome binding site AAGGAGG (McLaughlin et al., 1981).

This initiation codon was followed by a signal sequence-like sequence, and by use of the signal sequence cleavage model
15 proposed by Heijne (1983), the cleavage site could be predicted to be between the two alanine residues in the middle of the sequence Leu-Ala-Ala-Ala. The signal sequence of the Endo12 is thus 30 amino acids long.

20 The region upstream of the open reading frame contained a sequence homologous with the sigma 43 type promoters of B.subtilis (Johnson et al., 1983) at position 46-75.

This sequence consists of TTTACA as the -35 region and TATTAT as
25 the -10 region; the two are separated by 18 nucleotides.

A palindromic repeat sequence of 13 bp. was found downstream of the termination codon at position 1956-1981, which seems to resemble a rho-independent terminator (Rosenberg and Court,
30 1979).

Southern analysis

The Bacillus spp. (PL236) chromosomal DNA was digested with
35 HindIII, PstI, EcoRI and XhoI and the plasmid pPL382 was used as

a probe for the hybridization. The hybridization pattern obtained confirmed that the Bacillus spp. PL236 DNA was cloned in non-deleted form, that the two HindIII fragments from pPL382 was continuous on the Bacillus spp. PL236 chromosome and that the Endo2 gene was different from the other cloned endoglucanases.

Expression of Endo2 in B.subtilis

10 Plasmid pPL382 was transformed to B.subtilis DN1885 to achieve secretion of the mature Endo2 product. B. subtilis DN1885 (pPL382) was grown aerobically in 640 ml LB-medium containing 10 μ g/ml tetracycline for 30 hours. The supernatant was concentrated by precipitation for 24 hours with $(\text{NH}_4)_2\text{SO}_4$ at 70% saturation. After 5 hours of dialysis against 100 mM Tris-HCl pH 7, the concentrated supernatant was heated to 55°C for 15 minutes. Denatured protein was removed by centrifugation and the soluble proteins were subsequently precipitated with $(\text{NH}_4)_2\text{SO}_4$ at 70% saturation. The resolubilized proteins were dialyzed against 100 mM Tris-HCl pH 7 with a final volume of 2 ml and were applied to a 80 cm x 1 cm gel filtration column containing Ultrogel ACA 44 (LKB). Active fractions were pooled, concentrated and applied to a SDS containing polyacrylamide gel, where the endoglucanase appeared as a single band at 56 kDa. The activity yield of the method was approximately 10%.

The endoglucanase comigrates with the endoglucanase obtained from extracts of MC1000 (pPL382) as detected by Zymogram analysis in the supernatant of DN1885 (pPL382). The endoglucanase activity of DN1885 (pPL382) is about 25 times that of strain DN1885 when grown in NY medium.

EXAMPLE 3Endocellulase 35 Physical mapping of the endocellulase clone 3

The endocellulase clone 3 is represented by the plasmid pPL591 which contains a 11000 bp. EcoRI fragment of Bacillus spp. PL236 DNA. A partial restriction map of this plasmid is shown in Fig.

10 10. Zymogram analysis of extracts from E.coli MC1000(pPL591) shows that the insert gives rise to four proteins with cellulase activity. The approx. M_r of these proteins were 60000 D, 56000 D, 45000 D and 30000 D (Fig. 10).

15 Southern analysis showed that the EcoRI fragment from pPL591 was cloned in a non-deleted form from the Bacillus spp. PL236 chromosome, and indicates that the DNA did not contain the DNA-sequences encoding the Endo1 and Endo2 genes.

20 To analyse whether these proteins represented post-translational processing products from one or several cellulase genes, deletion plasmids were made using the restriction enzymes HindIII and SmaI. Deletion of the 4800 bp. SmaI fragment, resulting in the plasmid pPL538, did not eliminate any of the
25 four cellulase bands on the zymogram. The B.spp. DNA insert on pPL591 contained 5 HindIII sites. Digestion of pPL591 with HindIII thus gave 6 fragments of 6600 bp. (vector fragment), 3200 bp., 1700 bp., 1550 bp., 1350 bp. and 900 bp., where the 1700 bp. fragment had originated from the HindIII site within
30 the pUN121 vector plasmid (Fig. 11).

Elimination of all of the HindIII fragments except the 1700 bp. fragment (reinserted in the opposite direction) resulted in the plasmid pPL540. Removal of the rest of the Bacillus spp. PL236
35 DNA by eliminating the EcoRI fragment from pPL540 resulted in

the plasmid pPL587. Both the E.coli MC1000(pPL540) and the E.coli MC1000(pPL587) were cellulase-positive and zymogram analysis of extracts from these clones revealed only the 45000 D and 30000 D proteins. The protein-coding capacity of the Bacillus spp. PL236 DNA (approx. 1500 bp.) is approx. 55000 D, which is too small to contain two endoglucanase genes of 45000 D and 30000 D. The 30000 D protein on the zymogram is thus most likely a result of immature post-translational processing of the 45000 D protein. The cellulase gene encoding the 45000 D protein was designated Endo3A. The Endo3A gene was cloned in both directions on the plasmids pPL587 and pPL538 giving rise to the same two proteins, thus eliminating the chance of the protein being a fusion protein.

Elimination of the 1550 bp., the 1350 bp. and the 900 bp. fragment resulted in the plasmid pPL542. Extracts from E.coli MC1000(pPL542) revealed cellulase positive proteins of approx. 30000 D, 45000 D, 49000 D and 56000 D (Fig. 10). From these preliminary results, the existence of two additional endoglucanase genes within the original insert on pPL591 and pPL538 are postulated. The additional endoglucanase genes are designated Endo3B and Endo3C. Their postulated position on the Bacillus spp. PL236 DNA is shown in Fig. 11. The postulated model is based on the assumption that the 60000 D protein made from pPL538 and pPL591 is converted to a truncated fusion protein of 49000 D made from pPL542 where the HindIII fragment of 1350 bp. is deleted.

DNA-sequence of Endo3A

The DNA sequence of the Endo3A gene was deduced from the plasmid pPL540 containing approx. 1500 bp. of Bacillus spp. PL236 DNA using the dideoxy chain termination method. The gene was placed in pUC18 in both orientations, and a number of deletions were constructed. Standard primers were used except for one synthe-

tic oligonucleotide that was used for sequencing a region with no practical restriction sites.

The C-terminal part of the gene was deduced from the plasmid pPPL538. The partial DNA-sequence is shown in Sequence Listing ID#6. The sequence revealed an open reading frame coding for a protein with a M_r of about 62000 D which is in agreement with the observed protein of 60kD in the zymograms. The ATG start codon (position 30) is preceded by a typical ribosome binding site (McLaughlin et al., 1981). The initiation codon is followed by a typical gram-positive signal sequence and by using the signal sequence cleavage model (Heijne, 1983) a signal sequence of 36 amino acids is revealed.

15 EXAMPLE 4

Endocellulase 4

Zymogram analysis

20

The endocellulase clone No. 4 is represented by the plasmid pPPL592, which contains approx. 14000 bp. of Bacillus spp. PL236 DNA. A partial restriction map is shown in Fig. 1.

25 A zymogram analysis of extracts from E.coli MC1000(pPPL592= revealed three cellulase active proteins with M_r values of approx. 92000 D, 74000 D and 71000 D. Further analysis is necessary to determine whether these proteins are encoded by one or several cellulase genes.

30

Southern analysis confirmed the origin of the cloned DNA on the Bacillus spp. PL236 chromosome, and indicates that the cloned DNA is not represented on the other endoglucanase clones.

35

EXAMPLE 5A. Endol cloned and expressed in Bacillus subtilis

5 An agar slant was inoculated with B. subtilis strain CH 57 and
incubated for 20 hours at 37°C. 10 ml of a 0.9 % NaCl-solution
was added to the test tube which was shaken to suspend the
cells. The cell suspension was used to inoculate a 2 l
fermentor.

10

The following parameters were used to run the fermentation:

Temperature: 37°C.

15 Aeration: 1,1 l/minute.

Stirring: 1100 rpm.

Fermentor: A 2 l model with a working volume of 1,5 l.

20

The pH was maintained between 6.2 and 7.2 for the first 40 hours
of fermentation. After that the pH was maintained between 6.7
and 7.2. The pH was maintained within this range by dosing with
NH₃ and H₃PO₄.

25

Dosing of a glucose solution was initiated after 40 hours at a
flow rate of 3.7 ml/hour.

Substrate

| | | |
|----|---|--------|
| | Potato starch degraded with Termamyl* | 50 g |
| | Soybean meal | 110 g |
| 5 | Corn steep Liquor | 16.5 g |
| | Alburex (potato protein) | 27.5 g |
| | (NH ₄) ₂ SO ₄ | 2.2 g |
| | KH ₂ PO ₄ | 1,2 g |
| | Na ₂ HPO ₄ ·2H ₂ O | 5,9 g |
| 10 | Water added up to 1100 ml. | |

*Termamyl is a commercial B. licheniformis α -amylase available from Novo Nordisk A/S.

15 Glucose solution

| | | |
|--|---------------------------|-------|
| | Glucose·H ₂ O | 600 g |
| | Citric acid | 0,6 g |
| | Water added up to 1000 ml | |

20

The fermentation was stopped after 166 hours of fermentation at an OD₆₅₀ value of 122. At that time there were 1200 ml of fermentation broth in the fermentor.

- 25 The fermentation broth was centrifuged, and the extracellular volume was 400 ml containing 40 CMC-endoase units per ml (16.000 CMC-endoase units in all). The culture medium was further processed by filtration and dilution followed by concentration on an Amicon ultrafiltration module with a cut-off at 10.000 MW.
- 30 The concentrated enzyme solution was frozen.

- Half of the frozen liquid was thawed and diluted with deionized water and then concentrated once more on an Amicon ultrafiltration module. The total yield was 4471 CMC-endoase
- 35 units (from 8000 CMC-endoase units).

The total volume of 1050 ml was subjected to ion exchange chromatography at pH 7. The enzyme was bound to a DEAE-Sephacryl anion exchange column (300 ml volume) at pH 7 (50 mM tris-HCl). The Endo1 enzyme was eluted at pH 7 with 0.3 M NaCl.

The purified enzyme has a molecular weight of 58,000 D on SDS-PAGE. The pI is 4.0. Its activity is 30 CMC-endoase units per mg protein.

The protein determination is based on the amino acid composition of the enzyme deduced from the DNA sequence: 13 tryptophan, 30 tyrosine and a molecular weight of 57,566 D. The extinction coefficient is calculated by means of the following formula:

$$(13 \times 5559 + 30 \times 1197) / 57566 = 1.88$$

The purified enzyme has an endoglucanase activity of 57 CMC-endoase units-per ml and an absorbance at 280nm of 3.6.

Thus, $(57 \times 1.88)/3.6 = 30$ CMC-endoase units per mg protein.

B. Stability of Endo1 in detergents

The following 4 detergent compositions were used:

1. USA liquid detergent: 2 gram per liter of 6° hardness water (1 part tap water to 2 parts deionized water). The pH was measured to 7,29.
2. USA Heavy Duty Powder detergent: 0,9 gram per liter of 6° hardness water. The pH was measured to 9,2.
3. Heavy Duty Powder detergent (2) with bleach and activator: 0.12 gram/l Na-perborate tetrahydrate and 0,088 gram/l NOBS. The pH was measured to 9,2.

4. European Heavy Duty Powder detergent with bleach and activator (Batch DR 8806 Europe). 5 gram per liter in 9° hardness water.

5

CelluzymeTM (batch CAX 007 crude enzyme with cellulase and other enzymes) 2353 CMC-endoase units per gram was compared with Endol 30000 CMC-endoase units per gram.

10 The enzymes were diluted to 3 CMC-endoase units per ml in all 4 detergent solutions: The endoglucanase activity after dilution was measured as described above (by determining the decrease in the viscosity of CMC). The endoglucanase activity after 60 min. incubation at 40 °C was measured and compared with the initial
15 activity. The following results were obtained:

| | | | | |
|-------------------------|------|-----|-----|-----|
| Detergent solution | 1 | 2 | 3 | 4 |
| Celluzyme TM | 89% | 75% | 66% | 75% |
| <u>Endol</u> | 106% | 90% | 97% | 98% |

20

The standard deviation is 10%.

25

It appears from the table that Endol is more stable at a pH of 9-10 compared with CelluzymeTM in these detergents.

EXAMPLE 6

30

A. Preparation of full-length (~75 kD) Endol in B. subtilis

10 1 of LB medium containing 1 mM CuCl₂ and 10 µg/ml chloramphenicol was inoculated with 10 ml of an overnight
35 culture of B. subtilis DN969 (B. Diderichsen et al.,

J.Bacteriol. 172(8), 1990, pp. 4315-4321) containing the plasmid pCH7 (described above in example 1), divided among 10 sterile 2 l flasks and incubated with vigorous shaking for 36 hours at 37°C. The culture was centrifuged for 10 minutes at 10000xg and 4°C after which EDTA, pH 8, was added to the supernatant to a final concentration of 5 mM.

25 g of Avicel PH-105 which had been hydrated in ethanol and washed with distilled water was added to the supernatant which was left standing with gentle stirring for 2 hours at 4°C. The supernatant/Avicel mixture was centrifuged for 10 minutes at 10000xg and 4°C. The cleared supernatant was decanted off immediately after the rotor had stopped.

The Avicel/enzyme cake was resuspended and washed in 200 ml of 1mM EDTA, and the mixture was centrifuged for 1 minute at 10000xg. This procedure was repeated twice. The Avicel/enzyme cake was then resuspended in 150 ml (1% triethylamine and 1 mM EDTA) and was left standing with vigorous stirring for 1 hour at 4°C. The mixture was centrifuged for 1 minute at 10000xg and 4°C. The supernatant was retained. This procedure was repeated twice.

The solution of enzyme and triethylamine (about 300 ml) was evaporated in vacuo to 100 ml. The temperature of the solution was not allowed to exceed 10°C. The pH was adjusted to 7 by adding 1M HCl, and the solution was frozen at -70°C.

The amount of protein in the 100 ml enzyme solution was determined to be 40 mg by means of a Bradford reagent (available from BioRad) using bovine serum albumin as the standard.

B. Characterisation of the ~75 kD EndoI

The enzyme obtained above had a purity of about 90%. The enzyme

was found to have a molecular weight of 75 kD on SDS-PAGE.

In immunoprecipitation experiments (carried out by rocket immunoelectrophoresis in agarose gel as described by N. Axelsen et al., Chapter 2 in A Manual of Quantitative Immunoelectrophoresis, Blackwell Scientific Publ. 1973), ~75 kD Endo1 was immunoreactive with a monospecific rabbit antibody raised against the core region (~58 kD form) of Endo1.

- 10 The ~75 kD and ~58 kD (processed) forms of Endo1 were tested for their ability to bind to cellulose (Avicel). 10 µg of each of ~75 kD Endo1 and ~58 kD Endo1 were added to 50 µl of a cellulose suspension (0.1% w/w Avicel, 5 mM EDTA, pH 8.0). The suspensions were shaken for 30 minutes, and the Avicel was harvested at 15 10000 rpm for 2 minutes. The amount of Endo1 cellulase remaining in the supernatant was analysed by SDS-PAGE. More than 95% of the ~75 kD Endo1 was bound to the cellulose, while less than 5% of the ~58 kD Endo1 was similarly bound. This shows that the C-terminal part of the ~75 kD Endo1 cellulase comprises a 20 cellulose-binding domain.

Extensive amino acid sequence homology was found between this region (from amino acid 554 to 700) of the Endo1 cellulase and other cellulases, e.g. an endocellulase from Bacillus subtilis 25 (Nakamura et al., 1987), the middle part of the bifunctional cellulase from Caldocellum saccharolyticum (D.J. Saul et al., Nucl.Acids Res. 17, 1988, p. 439), two endocellulases from Clostridium stercorarium (W. Schwarz et al., Biotech.Lett. 11, 1989, pp. 461-466).

30

C. Colour clarification effect of ~75 kD Endo1

The colour clarification effect of ~75 kD Endo1 was determined by exposing a prewashed worn textile surface to the enzyme and 35 then measuring the clarity of the surface colour compared to the

clarity of the surface colour of textiles which had not been treated with the enzyme.

Black 100% cotton swatches (15 x 10 cm) were prewashed and
5 tumble-dried under the following conditions

Detergent: Keminus (available from Irma A/S),
1.5g/l
Temperature: 70°C
10 Washing time: 60 minutes
Drying time: 30 minutes
No. prewashing/
drying treatments:15

15 The swatches were prewashed in a conventional washing machine
(Miele Deluxe Electronic W761). After each wash, the swatches
were dried in a tumble-drier. The visual effect of the
prewashing/drying was that the surface colour turned greyish due
to the presence of damaged cellulose fibres causing the worn
20 look.

After prewashing, the swatches were washed in a Terg-O-Tometer
(toploaded mini washing machine) under the following conditions

25 Liquid volume: 800 ml
Agitation: 100 movements/minute
Detergent: Standard detergent, 5g/l
Washing time: 30 minutes
Washing tempera-
30 ture: 40°C
No. of swatches: 2
~75 kD Endo1
dosage: 0 and 60 CMC endoase units/l
pH: 7.0
35 No. of treatments:3

Standard detergent:

| | | |
|---|-------------------|-----|
| | LAS NANSA 1169/P: | 10% |
| 5 | AE Berol 160: | 15% |
| | Ethanol, 96%: | 10% |
| | TEA: | 5% |
| | Water: | 60% |

- 10 After each wash, the swatches were rinsed in tap water and dried at room temperature.

The surface colour of the swatches was analysed by measuring reflected light. White light was projected onto the surface, and
 15 the reflection/remission was measured at 16 wavelengths (400 nm - 700 nm). The results from the measurements were processed (by means of an "Elrepho 2000" apparatus available from Datacolor, Switzerland) into Hunter coordinates of which the L-coordinate represents the grey scale values. Each swatch was analysed twice
 20 on each side, and the results shown below are a total average from the measurements of the two swatches from the same treatment. In the table, white is L = 100, and black is L = 0.

| | | | |
|----|---------|---------------------------------|-------|
| | Dosage | 0 CMC endoase/160 CMC endoase/l | |
| 25 | L | 16.78 | 15.50 |

International Application No: PCT/

| MICROORGANISMS | |
|---|--------------------|
| Optional Sheet in connection with the microorganism referred to on page <u>3</u> , line <u>20</u> of the description 1 | |
| A. IDENTIFICATION OF DEPOSIT : | |
| Further deposits are identified on an additional sheet <input type="checkbox"/> | |
| Name of depository institution * | |
| NATIONAL COLLECTION OF INDUSTRIAL & MARINE BACTERIA LTD. | |
| Address of depository institution (including postal code and country) * | |
| Torry Research Station, P.O. Box 31, 23 St Machar Drive, Aberdeen AB9 8DG, Scotland | |
| Date of deposit * | Accession Number * |
| 18 January 1990 | NCIMB 40250 |
| B. ADDITIONAL INDICATIONS * (leave blank if not applicable). This information is continued on a separate attached sheet <input type="checkbox"/> | |
| <p>In respect of those designations in which a European patent is sought, a sample of the deposited micro-organism will be made available only by the issue of such a sample to an expert nominated by the person requesting the sample (Rule 28(4) EPC) until the publication of the mention of the grant of the European patent or until the date on which the application has been refused or is deemed to be withdrawn.</p> | |
| C. DESIGNATED STATES FOR WHICH INDICATIONS ARE MADE * (if the indications are not for all designated States) | |
| | |
| D. SEPARATE FURNISHING OF INDICATIONS * (leave blank if not applicable) | |
| The indications listed below will be submitted to the International Bureau later * (Specify the general nature of the indications e.g., "Accession Number of Deposit") | |
| | |
| E. <input checked="" type="checkbox"/> This sheet was received with the international application when filed (to be checked by the receiving Office) | |

CLAIMS

1. An enzyme which exhibits cellulase activity, which enzyme is producible by a strain of Bacillus spp., NCIMB 40250, or a related Bacillus spp. strain,
5 or a derivative of said cellulase.
2. An enzyme according to claim 1, which exhibits an endoglucanase activity of at least about 10, more preferably at least about 20, most preferably at least about 25, such as about 30, CMC-endoase units (as defined herein) per
10 mg of total protein under alkaline conditions.
3. An enzyme according to claim 1, which is active at a temperature of up to about 65 °C.
- 15 4. An enzyme according to any of claims 1-3, which is an endoglucanase with an apparent molecular weight of 75 kD or a cleavage product thereof exhibiting endoglucanase activity.
5. An enzyme according to claim 4, which is an endoglucanase encoded by the
20 DNA sequence shown in the appended Sequence Listing ID#1, or a modification thereof encoding a derivative of said endoglucanase.
6. An enzyme according to any of claims 1-3, which is an endoglucanase with an apparent molecular weight of 56 kD or a cleavage product thereof
25 exhibiting endoglucanase activity.
7. An enzyme according to claim 6, which is an endoglucanase encoded by the DNA sequence shown in the appended Sequence Listing ID##, or a modification thereof encoding a derivative of said endoglucanase.
30
8. An enzyme according to any of claims 1-3, which is an endoglucanase with an apparent molecular weight of 45 kD or a cleavage product thereof exhibiting endoglucanase activity.

9. An enzyme according to claim 8, which is an endoglucanase encoded by the DNA sequence shown in the appended Sequence Listing ID#6, or a modification thereof encoding a derivative of said endoglucanase.
- 5 10. An enzyme according to any of claims 1-3, which is an endoglucanase with an apparent molecular weight of 60 kD or a cleavage product thereof exhibiting endoglucanase activity, or which is an endoglucanase with an apparent molecular weight of 56 kD or a cleavage product thereof exhibiting endoglucanase activity.
- 10 11. An enzyme according to any of claims 1-3, which is an endoglucanase with an apparent molecular weight of 92 kD or a cleavage product thereof exhibiting endoglucanase activity.
- 15 12. An enzyme which comprises a core region derived from an endoglucanase according to any of claims 1-11 combined with a cellulose-binding domain derived from another cellulase enzyme, or a core region derived from another cellulase enzyme combined with a cellulose-binding domain derived from an endoglucanase according to any of claims 1-11.
- 20 13. An enzyme according to claim 12, wherein the core region is derived from a cellulase enzyme which does not, in nature, comprise a cellulose-binding domain.
- 25 14. A DNA construct which comprises a DNA sequence encoding an enzyme exhibiting cellulase activity, which enzyme is derivable from a strain of Bacillus spp., NCIMB 40250, or a related Bacillus spp. strain, or a derivative of said cellulase.
- 30 15. A DNA construct according to claim 14, wherein the DNA sequence encodes an endoglucanase with an apparent molecular weight of 75 kD.
- 35 16. A DNA construct according to claim 15, wherein the DNA sequence is the one shown in the appended Sequence Listing ID#1, or a modification thereof encoding a derivative of said endoglucanase.

17. A DNA construct according to claim 14, wherein the DNA sequence encodes an endoglucanase with an apparent molecular weight of 56 kD.
- 5 18. A DNA construct according to claim 17, wherein the DNA sequence is the one shown in the appended Sequence Listing ID#3, or a modification thereof encoding a derivative of said endoglucanase.
- 10 19. A DNA construct according to claim 14, wherein the DNA sequence encodes an endoglucanase with an apparent molecular weight of 45 kD.
- 15 20. A DNA construct according to claim 19, wherein the DNA sequence is the one shown in the appended Sequence Listing ID#6, or a modification thereof encoding a derivative of said endoglucanase.
21. A DNA construct according to claim 14, wherein the DNA sequence encodes an endoglucanase with an apparent molecular weight of 92 kD.
- 20 22. An expression vector which carries an inserted DNA construct according to any of claims 14-21.
23. A cell which is transformed with a DNA construct according to any of claims 14-21 or with an expression vector according to claim 22.
- 25 24. A cell according to claim 23, which is a bacterium.
25. A cell according to claim 24, which is a grampositive bacterium.
- 30 26. A cell according to claim 25, wherein the grampositive bacterium is selected from the group consisting of Bacillus subtilis, Bacillus licheniformis, Bacillus lentus, Bacillus brevis, Bacillus stearothermophilus, Bacillus alkalophilus, Bacillus amyloliquefaciens, Bacillus coagulans, Bacillus circulans or Bacillus lautus.

27. A cell according to claim 24, which is a gramnegative bacterium, e.g. Escherichia coli.

28. A method of producing an enzyme according to any of claims 1-13, wherein
5 a host cell according to any of claims 23-27 is cultured under conditions conducive to the production of the endoglucanase or a derivative thereof, and the endoglucanase or derivative thereof is subsequently recovered from the culture.

10 29. A method according to claim 28, wherein the endoglucanase is recovered in mature form.

30. A cellulolytic agent capable of degrading amorphous regions of cellulose
15 fibres, the agent comprising an enzyme according to any of claims 1-13.

31. An agent according to claim 30, which comprises a combination of two or more cellulases recited in any of claims 1-13, or a combination of one or more cellulases recited in any of claims 1-13 with one or more other enzymes with cellulase activity.

20 32. An agent according to claim 30 or 31, which is in the form of a non-dusting granulate, stabilized liquid or protected enzyme.

25 33. An agent according to any of claims 30-32, which exhibits an endoglucanase activity of 500-10,000 CMC-endoase units per gram of the agent.

34. An agent according to any of claims 30-33, which is a detergent additive.

30 35. An agent according to claim 34, which additionally comprises another enzyme such as a protease, lipase and/or amylase.

36. A detergent composition comprising a cellulolytic agent according to any of claims 30-35.

37. A detergent composition according to claim 36, which exhibits an endoglucanase activity of 0.3-400 CMC-endoase units per gram of detergent.
38. A method of reducing the rate at which cellulose-containing fabrics become harsh or of reducing the harshness of cellulose-containing fabrics, the method comprising treating cellulose-containing fabrics with a cellulolytic agent according to any of claims 30-35.
39. A method according to claim 38, wherein the treatment of the fabrics with the cellulolytic agent is conducted during soaking, washing or rinsing of the fabrics.
40. A method of treating a coloured, cellulose-containing fabric in order to provide colour clarification, the method comprising treating the cellulose-containing fabric with a cellulolytic agent according to any of claims 30-35.
41. A method according to claim 40, wherein the treatment of the fabric with the cellulolytic agent is conducted in an aqueous medium during soaking, washing or rinsing of the fabric.
42. A method according to claim 41, wherein the aqueous medium exhibits an endoglucanase activity of more than about 250 CMC-endoase units per liter of the aqueous medium.

FURTHER INFORMATION CONTINUED FROM THE SECOND SHEET

/partly/

V. ☒ OBSERVATIONS WHERE CERTAIN CLAIMS WERE FOUND/UNSEARCHABLE¹

This international search report has not been established in respect of certain claims under Article 17(2) (a) for the following reasons:

1. ☐ Claim numbers....., because they relate to subject matter not required to be searched by this Authority, namely:

2. ☒ Claim numbers 1, 14, because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
 The wording of these claims are too broadly formulated to permit a meaningful search of the whole claims.

3. ☐ Claim numbers....., because they are dependent claims and are not drafted in accordance with the second and third sentences of PCT Rule 6.4(a).

VI. ☒ OBSERVATIONS WHERE UNITY OF INVENTION IS LACKING²

This International Searching Authority found multiple inventions in this international application as follows:

1. ☒ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims of the international application.
2. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims of the international application for which fees were paid, specifically claims:
3. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the the claims. It is covered by claim numbers:
4. ☐ As all searchable claims could be searched without effort justifying an additional fee, the International Searching Authority did not invite payment of any additional fee.

Remark on Protest

- ☐ The additional search fees were accompanied by applicant's protest.
☐ No protest accompanied the payment of additional search fees.

**ANNEX TO THE INTERNATIONAL SEARCH REPORT
ON INTERNATIONAL PATENT APPLICATION NO. PCT/DK 91/00013**

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report. The members are as contained in the Swedish Patent Office EDP file on **91-03-23**.
The Swedish Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
